## **Module 6 Cheat Sheet: Monitoring and Tuning**

```
Package/Method
                         Description
                                                                                              Code Example
                      Used to get the
                                           1. 1
                      aggregate values
                      like count, sum,
                                           1. agg_df = df.groupBy("column_name").agg({"column_to_aggregate": "sum"})
agg()
                      avg, min, and
                      max for each
                                         Copied!
                      group.
                      Apache Spark
                      transformation
                      that is often used
                      on a DataFrame,
                      data set, or RDD
                      when you want
                      to perform more
                      than one action.
                      cache() caches
                      the specified
                      DataFrame, data
                      set, or RDD in
                      the memory of
                                           2. 2
                      your cluster's
                                           1. df = spark.read.csv("customer.csv")
cache()
                      workers. Since
                                           2. df.cache()
                      cache() is a
                      transformation,
                                        Copied!
                      the caching
                      operation takes
                      place only when
                      a Spark action
                      (for example,
                      count(), show(),
                      take(), or write())
                      is also used on
                      the same
                      DataFrame,
                      Dataset, or RDD
                      in a single action.
                                        Basic syntax of the cd command:
                                           1. 1

    cd [options]... [directory]

                                        Copied!
                                        Example 1: Change directory location to folder1.
                                           1. 1
                      Used to move

    cd /usr/local/folder1

                      efficiently from
                      the existing
                                        Copied!
                      working
cd
                      directory to
                                        Example 2: Get back to the previous working directory.
                      different
                      directories on
                                           1. 1
                      your system.
                                           1. cd -
                                        Copied!
                                        Example 3: Move up one level from the present working directory tree.
                                           1. 1
                                           1. cd ..
                                         Copied!
                      Used to define a
                                           1. 1
def
                      function. It is
                                           1. def greet(name):
                      placed before a
                      function name
                                         Copied!
                      that is provided
                      by the user to
                                        This function takes a name as a parameter and prints a greeting.
                      create a user-
                      defined function.
                                           1. print(f"Hello, {name}!")
                                        Copied!
                                        Calling the function:
```

about:blank 1/5

7/11/24, 4:19 PM about:blank

```
Package/Method
                                                                                                   Code Example
                          Description
                                            1. 1

    greet("John")

                                          Copied!
                       Runs a new
                       command in a
                       running
                                            1. 1
2. 2
                       container. Only
                       runs while the

    docker exec -it container_name command_to_run
    docker exec -it my_container /bin/bash

docker exec
                       container's
                       primary process
                       is running, and it
                                           Copied!
                       is not restarted if
                       the container is
                       restarted.
                                          To remove a single container by name or ID:
                                            1. 1

    docker rm container_name_or_id

                                          Copied!
                                          To remove multiple containers by specifying their names or IDs:
                       Used to remove
docker rm
                       one or more

    docker rm container1_name_or_id container2_name_or_id

                       containers.
                                          Copied!
                                          To remove all stopped containers:
                                            1. 1

    docker rm $(docker ps -aq)

                                          Copied!
                       It runs a
                       command in a
                                            1. 1
                       new container,

    docker run [OPTIONS] IMAGE [COMMAND] [ARG...]

docker run
                       getting the image
                       and starting the
                                           Copied!
                       container if
                       needed.
                                            1. 1
                                             1. fruits = ["apple", "banana", "cherry"]
                       The for loop
                       operates on lists
                                          Copied!
                       of items. It
                       repeats a set of
for
                                          Iterating through the list using a for loop for fruit in fruits:
                       commands for
                       every item in a
                       list.

    print(f"I like {fruit}s")

                                          Copied!
                                            1. import pandas as pd
                                          Copied!
                                          Sample DataFrame:
                       Used to collect
                       the identical data
                                            3. 3
                       into groups on
                                            1. data = {'Category': ['A', 'B', 'A', 'B', 'A', 'B'], 2. 'Value': [10, 20, 15, 25, 30, 35]}
                       DataFrame and
groupby()
                       perform count,
                                             3. df = pd.DataFrame(data)
                       sum, avg, min,
                       max functions on Copied!
                       the grouped data.
                                          Grouping by "Category" and performing aggregation operations:
                                            1. 1
                                            2. 2
                                             1. grouped = df.groupby('Category').agg({'Value': ['count', 'sum', 'mean', 'min', 'max']})
                                             print(grouped)
                                           Copied!
```

about:blank 2/5

Package/Method Description Code Example Create a sample DataFrame: 2. 2 3. 3 1. data = [("John", 25), ("Peter", 30), ("Julie", 35), ("David", 40), ("Eva", 45)]
2. columns = ["Name", "Age"] 3. df = spark.createDataFrame(data, columns) Copied! Show the current number of partitions. 1. 1 Used to increase 1. print("Number of partitions before repartitioning: ", df.rdd.getNumPartitions()) or decrease the Copied! RDD or DataFrame Repartition the DataFrame to 2 partitions. partitions by repartition() number of 1. 1 partitions or by a single column 1. df\_repartitioned = df.repartition(2) name or multiple Copied! column names. Show the number of partitions after repartitioning. 1. 1 print("Number of partitions after repartitioning: ", df\_repartitioned.rdd.getNumPartitions()) Copied! Stop the SparkSession. 1. 1 1. spark.stop() Copied! 1. 1 2. 2 3. 3 1. def add\_numbers(a, b): result = a + b3. return result Copied! Calling the function and capturing the returned value: Used to end the execution of the function call and 1. sum\_result = add\_numbers(5, 6) returns the result Copied! (value of the return expression Printing the result. following the return keyword) to the caller. 1. print("The sum is:", sum\_result) Copied! Output. 1. 1 1. The sum is: 11 Copied! Spark DataFrame show() is used to display the contents of the DataFrame in a 1. 1 table row and df.show() show() column format. By default, it Copied! shows only 20 rows, and the column values are truncated at 20 characters.

```
Package/Method
                                                                                                  Code Example
                          Description
                                            1. 1

    from pyspark.sql import SparkSession

                                          Copied!
                                         Create a SparkSession.
                                            1. 1
                                            1. spark = SparkSession.builder.appName("CSVReadExample").getOrCreate()
                                          Copied!
                       Using this, you
                                         Read a CSV file into a Spark DataFrame.
                       can read a CSV
                       file with fields
                       delimited by
                                            1. df = spark.read.csv("path_to_csv_file.csv", header=True, inferSchema=True)
spark.read.csv("path")
                       pipe, comma, tab
                       (and many more)
                                         Copied!
                       into a Spark
                                         Show the first few rows of the DataFrame.
                       DataFrame.
                                            1. 1

    df.show()

                                          Copied!
                                         Stop the SparkSession.
                                            1. 1

    spark.stop()

                                          Copied!
                                         Basic syntax of the wget command; commonly used options are [-V], [-h], [-b], [-e], [-a], [-q]
                                            1. wget [options]... [URL]...
                       Stands for web
                                          Copied!
                       get. The wget is a
                       free
                                         Example 1: Specifies to download file.txt over HTTP website URL into the working directory.
                       noninteractive
                       file downloader
                       command.
wget

    wget http://example.com/file.txt

                       Noninteractive
                       means that it can
                                          Copied!
                       work in the
                       background
                                         Example 2: Specifies to download the archive.zip over HTTP website URL in the background and returns you to the command
                       when the user is
                                         prompt in the interim.
                       not logged in.
                                            1. wget -b http://www.example.org/files/archive.zip

withColumn()
                       Transformation
                                         Sample DataFrame:
                       function of
                       DataFrame
                                            2. 2
                       which is used to
                       change the value,
                                            1. data = [("John", 25), ("Peter", 30), ("David", 35)]
2. columns = ["Name", "Age"]
3. df = spark.createDataFrame(data, columns)
                       convert the
                       datatype of an
                       existing column,
                       create a new
                                          Copied!
                       column, and
                       many more.
                                         Using withColumn to create a new column and change values
                                            2. 2
3. 3
                                            4. 4
                                            5.5
                                            6. 6
7. 7
                                            1. updated_df = df \
                                                    .wiThColumn("DoubleAge", col("Age") * 2) # Create a new column "DoubleAge" by doubling the "Age" column
                                            2.
                                            3. updated df = updated df \
                                                    .withColumn("AgeGroup", when(col("Age") <= 30, "Young")
    .when((col("Age") > 30) & (col("Age") <= 40), "Middle-aged")</pre>
                                            4.
                                                                  .otherwise("Old")) # Create a new column "AgeGroup" based on conditions
                                               updated_df.show()
